## **Data Analysis with Python**

## **Cheat Sheet: Model Evaluation and Refinement**

```
Process
                                          Description
                                                                                                                                                                             Code Example
                                The process involves
                                first separating the
                                                                                2. 2
3. 3
                                target attribute from
                                the rest of the data.
Splitting data for Treat the target

    from sklearn.model_selection import train_test_split

                                attribute as the output
training and
                                                                                2. y_data = df['target_attribute']
3. x_data=df.drop('target_attribute',axis=1)
testing
                                and the rest of the data
                                as input. Now split the
                                                                                4. x_train, x_test, y_train, y_test = train_test_split(x_data, y_data, test_size=0.10, random_state=1)
                                input and output
                                datasets into training
                                                                            Copied!
                                and testing subsets.
                                                                                2. 2 3. 3
                                Without sufficient
                                data, you go for cross
                                validation, which
                                involves creating
                                different subsets of
Cross validation

    from sklearn.model_selection import cross_val_score
    from sklearn.linear model import LinearRegression lre=LinearRegression()

                               training and testing
score
                                data multiple times
                                                                                3. Rcross = cross_val_score(lre,x_data[['attribute_1']],y_data,cv=n)
                                and evaluating
                                                                                4. # n indicates number of times, or folds, for which the cross validation is to be done
                                performance across all
                                                                                5. Mean = Rcross.mean()
                                of them using the R<sup>2</sup>
                                                                                6. Std_dev = Rcross.std()
                                value.
                                                                            Copied!
                                                                                1. 1
                                                                                3. 3
                                                                                4. 4
                                Use a cross validated
Cross validation model to create
                                                                                1. from sklearn.model selection import cross val score
                                prediction of the
prediction
                                                                                2. from sklearn.linear_model import LinearRegression
                                output.
                                                                                3. lre=LinearRegression()
                                                                                4. yhat = cross_val_predict(lre,x_data[['attribute_1']], y_data,cv=4)
                                                                            Copied!
                                To create a better
                                                                                1. 1
                                fitting polynomial
                                                                                3. 3
                                regression model, like
                                                                                4. 4
5. 5
                                , one that avoids
                                overfitting to the
Ridge
                                training data, we use
                               the Ridge regression

    from sklearn.linear_model import Ridge

Regression and
                                                                                1. Troin sate in Title in index in the
